18 sectional study

19

20 **Abstract:** There are a few studies on the association between type 2 diabetes (T2D) and  
21 the gut microbiota but no community-based cross-sectional study. In the Iwaki Health  
22 Promotion Project (Hirosaki, Japan), we surveyed medical information and lifestyle and  
23 analyzed the gut microbiota using the terminal restriction fragment length  
24 polymorphism technique or next-generation sequencing. Based on these data,  
25 multivariable logistic regression analysis was performed with or without T2D as the  
26 dependent variable. Consequently, it was suggested that the *Lactobacillales* population  
27 in the gut microbiota was positively associated with T2D, consistent with the results of  
28 case-control studies.

29

30 Type 2 diabetes (T2D) is caused by insulin resistance or impaired insulin secretion. T2D  
31 is related to genetic factors and lifestyle, such as overeating or lack of exercise. In Japan,  
32 the sum of patients with T2D and potential diabetics was 20 million in 2016 (The  
33 National Health and Nutrition Survey in Japan, 2018). The prevalence is higher in males  
34 and with increasing years.

35 Research on the association between various diseases and the gut microbiota has  
36 advanced [1] and become increasingly important. Also, case-control studies on the  
37 association between T2D and the gut microbiota have been reported [2-10]. These studies  
38 commonly indicated an increased *Lactobacillales* population in the fecal microbiota in  
39 T2D, so *Lactobacillales* have the potential to be a novel target for prevention and therapy  
40 of T2D.

41

42 Community-based health examination surveys (in Hirosaki, Japan) have been  
43 performed for many years, called “the Iwaki Health Promotion Project.” In this project,  
44 about ten hundreds of people participate every year, and data from more than 2000 items

45 related to vital and medical information, dietary habits, and lifestyle are collected. These  
46 also include data on the gut microbiota obtained using the terminal restriction fragment  
47 length polymorphism (T-RFLP) technique [11, 12] or next-generation sequencing (NGS)  
48 [13].

49 There has been no community-based cross-sectional study on the association between  
50 T2D and the gut microbiota. Therefore, in this study, multivariable logistic regression  
51 analysis was performed with or without T2D as the dependent variable using Iwaki  
52 Health Promotion Project data.

53 This survey was intended for the Iwaki Health Promotion Project (in Hirosaki, Japan)  
54 participants in 2012, 2014, and 2016. Subjects were inquired about sex, age, medical  
55 history, drug intake, smoking, alcohol drinking, exercise, etc. Weight and height were  
56 measured to calculate the body mass index (BMI). The number of subjects by sex and  
57 age is indicated in Table 1. This study was approved by the Ethics Committee of Hirosaki  
58 University Graduate School of Medicine. Written informed consent was obtained from  
59 all participants.

60 Fecal DNA was prepared as described previously [14]. Feces were collected into a 4 M  
61 guanidine thiocyanate solution, followed by bead-beating and extraction using magnetic  
62 beads. The fecal microbiota was analyzed by T-RFLP [11, 12] or NGS [13], targeting the  
63 16S rRNA gene.

64 *In silico* T-RFLP using bacterial 16S rRNA gene sequences obtained by random cloning  
65 analysis of the fecal microbiota provided correspondence between operational taxonomic  
66 units (OTUs) in T-RFLP and phylogenetic bacterial groups [11, 12]. This study classified  
67 these OTUs into eight bacterial functional groups (B-1–B-8; see Table 2) based on the  
68 organic acid-producing activity [15]. Conversion equations are given below.

69  $B1 = OTU366 + OTU469 \times 0.97 + OTU853$

70  $B2 = OTU317$

71  $B3 = OTU106 + OTU168 + OTU338 + OTU369 \times 0.33 + OTU494 \times 0.84 + OTU650 +$   
72  $OTU657 \times 0.08 + OTU754 \times 0.52 + OTU920 \times 0.8 + OTU940 \times 0.28 + OTU955 \times 0.92$

73  $B4 = OTU124$

74  $B5 = OTU332 + OTU520 + OTU657 \times 0.92$

75  $B6 = OTU369 \times 0.33 + OTU494 \times 0.14 + OTU505 \times 0.5 + OTU517 + OTU640 + OTU749$   
76  $+ OTU754 \times 0.1 + OTU940 \times 0.24 + OTU955 \times 0.08$

77  $B7 = OTU110 \times 0.96 + OTU369 \times 0.17 + OTU469 \times 0.03$

78  $B8 = OTU369 \times 0.17 + OTU494 \times 0.02 + OTU505 \times 0.5 + OTU754 \times 0.38 + OTU920 \times$   
79  $0.2 + OTU940 \times 0.48 + OTU990$

80 Multivariable logistic regression analysis (forward selection method) was performed  
81 with or without T2D as the dependent variable. The number of subjects with or without  
82 T2D and with healed T2D is shown in Table 3. Subjects with healed T2D were excluded  
83 from the analysis due to the difficulty of attributing to either of the binary variables. The  
84 functional bacterial groups in Table 2 in T-RFLP or seven orders, including *Bacteroidales*,  
85 *Bifidobacteriales*, *Clostridiales*, *Coriobacteriales*, *Enterobacteriales*, *Lactobacillales*, and  
86 *Selenomonadales*, in NGS were the independent variables. The sequences derived from  
87 these seven orders accounted for >90% of the total. Age, BMI, smoking, alcohol drinking,  
88 and exercise were used as moderators in the regression analysis. In 2016, when subjects  
89 were inquired about drug intake,  $\alpha$ -glucosidase inhibitor ( $\alpha$ -GI), a diabetes drug, was also  
90 used as a moderator. JUSE-StatWorks/V5E (The Institute of JUSE, Tokyo, Japan) was  
91 used for statistical analysis. The significance level was set at  $p < 0.05$ .

92

93 In Table 3, the T2D ratio in subjects was 3.5% to 4.2% in females and 7.2% to 7.5% in

94 males, which is almost the same level as the ratio of outpatients with T2D to the  
95 population (>20 years old in 2016) in Aomori Prefecture: 3.1% in females and 5.4% in  
96 males

97 This study used multivariable logistic regression to assess the association between T2D  
98 and the gut microbiota (OTUs) in the Iwaki Health Promotion Project participant  
99 population for 3 years. A summary of the results is presented in Table 4. The functional  
100 bacterial group B-5 (*Lactobacillales*, refer to Table 2) was commonly extracted as a  
101 significant variable in males and females in case of 2012 and 2014, in which T-RFLP  
102 analysis was performed, with odds ratios [OR; 95% confidence intervals (95% CIs)] was  
103 1.062 (1.025–1.100), 1.068 (1.019–1.20), 1.085 (1.032–1.142), and 1.069 (1.020–1.121),  
104 respectively. In case of 2016, in which NGS analysis was performed, *Lactobacillales* was  
105 a significant variable in males with ORs (95% CIs) of 1.174 (1.019–1.351), but it was an  
106 insignificant variable in females, with p-value of a slightly over 10% ( $p = 0.109$ ). The  
107 functional bacterial group B-4 (*Bifidobacterium* spp.) was also a significant variable in  
108 some cases, that is, males and females in 2012 and males in 2014 and 2016, with ORs  
109 (95% CIs) of 1.150 (1.064–1.244), 1.075 (1.007–1.146), 1.053 (1.013–1.095), and 1.074  
110 (1.024–1.125), respectively. As for the rest, the functional bacterial group B-3  
111 (*Clostridium* clusters IV, XI, XIVa, and XVIII) in females in 2014, *Bifidobacterium* and  
112 *Coriobacteriales* in males in 2016, and *Bacteroidales* in females in 2016 were significant  
113 variables.

114

115 Although previous studies on the association between T2D and the gut microbiota were  
116 performed in various countries (Austria, Iran, Denmark, Japan, and Sweden) with  
117 various techniques (NGS, quantitative polymerase chain reaction, and T-RFLP), a  
118 positive association with *Lactobacillales* was indicated in any studies, suggesting a

119 considerably high certainty of the results. In this study, a multivariable logistic  
120 regression analysis was performed to assess the association between T2D and the gut  
121 microbiota in a cross-sectional study intended for people in Hirosaki, Japan. Similar  
122 results to previous studies were obtained.

123 This and previous studies suggested the causal relationship between T2D and  
124 *Lactobacillales*, but the cause or result is unknown. First, whether *Lactobacillales* are  
125 innate bacteria or bacteria originating from foods, such as yogurt, was discussed. Sato et  
126 al. [6] and Adachi et al. [9] considered that these bacteria are innate because the number  
127 of subjects who consumed yogurt was not significantly different between the control and  
128 T2D groups and significantly fewer in the latter group. Furthermore, the number of  
129 probiotic bacteria taken from supplements or foods was  $\sim 10^{10}$  cells/day. These bacteria  
130 cannot colonize and proliferate in the gut to remain a minor population. Therefore, the  
131 idea that these bacteria are innate is deemed to be appropriate.

132 Morita et al. [16] indicated that lactate and pyruvate, produced in the small intestinal  
133 in a bacteria-dependent manner, enhanced immune responses by inducing dendrite  
134 protrusion of intestinal CX3CR1<sup>+</sup> mononuclear cells. These findings speculated a  
135 possible causal relationship as follows: an excess of bacteria, including lactic acid  
136 bacteria in the small intestine, induces the overstimulation of immune responses,  
137 followed by chronic inflammation, resulting in the T2D onset (17, 18).

138 If that is the case, why do bacteria such as lactic acid bacteria proliferate abnormally in  
139 the small intestine? Usually, gastric acid strongly prevents bacterial entry to the small  
140 intestine from the oral cavity so that almost no bacterial proliferation occurs. However,  
141 gastric acid secretion declines with aging or is decreased by stress, which is considered  
142 to cause the proliferation of these bacteria in the intestines [19-22].

143 On the one hand, some studies suggested that  $\alpha$ -GI increases *Bifidobacterium* spp. and

144 *Lactobacillales* population in the fecal microbiota [6, 9, 10]. In this project in 2016, the  
145 number of subjects with T2D who did or did not take  $\alpha$ -GI was 12 (10 males and 2  
146 females) and 45 (23 males and 22 females), respectively. *Bifidobacterium* spp. population  
147 in the fecal microbiota in males was higher in subjects with T2D taking  $\alpha$ -GI than those  
148 not taking  $\alpha$ -GI [mean  $\pm$  standard deviation (SD),  $24.3 \pm 7.9$  vs.  $9.3 \pm 11.0$ ;  $p = 0.003$ ,  
149 Wilcoxon rank-sum test]. Similarly, in *Lactobacillales* in males, the population was  
150 higher in subjects with T2D taking  $\alpha$ -GI (mean  $\pm$  SD,  $29.4 \pm 14.6$  vs.  $8.5 \pm 14.9$ ;  $p < 0.001$ ).  
151 No significant difference was observed in females. From these facts, here we accessed  
152 using  $\alpha$ -GI as an additional moderator for the regression analysis in 2016, in which  
153 subjects were inquired about drug intake.

154 On the other hand,  $\alpha$ -GI is not involved in the other studies that indicate the positive  
155 association between T2D and *Lactobacillales* [5, 7, 8]. Furthermore, the *Lactobacillales*  
156 population in the fecal microbiota also increased in a mouse model of insulin resistance  
157 [23]. Considering these findings,  $\alpha$ -GI is deemed to have only limited effectiveness in this  
158 and previous studies on the association between T2D and the gut microbiota.

159

160 Taken together, multivariable logistic regression analysis was performed in the  
161 community-based cross-sectional study to assess the association between T2D and the  
162 gut microbiota. It was suggested that the *Lactobacillales* population was positively  
163 related to T2D, as indicated in previous studies. It is expected that future analyses will  
164 be performed with more subjects, and studies on the elucidation of the causal  
165 relationship are making progress. As such, novel techniques for prevention and therapy  
166 targeted to the bacteria are being developed.

\* In silico T-RFLP using the 16S rRNA gene sequences obtained by the random cloning analysis of fecal microbiota provides a correspondence between the OTUs in T-RFLP and the phylogenetic bacterial groups (11, 12). In this research, these OTUs were further classified into the 8 bacterial functional groups (B-1 to B-8) on the basis of the organic acid producing activity. Even if the clones from the bacterial 16S rRNA gene belong to the same OTU, they are allocated to the different functional group in some cases because of the different organic acid producing activity. Numbers in parentheses indicate the allocation ratios (%), which were calculated from the number of clones belonging to each functional group.

Table 3. The number of subjects with or without T2D and with healed T2D by sex and years

| T2D     |        | 2012 |           | 2014 |           | 2016 |           |
|---------|--------|------|-----------|------|-----------|------|-----------|
|         |        | No.  | Ratio (%) | No.  | Ratio (%) | No.  | Ratio (%) |
| With    | Male   | 25   | 7.2       | 31   | 7.3       | 33   | 7.5       |
|         | Female | 21   | 3.6       | 29   | 4.2       | 24   | 3.5       |
| Without | Male   | 323  | 92.6      | 388  | 91.5      | 405  | 91.6      |
|         | Female | 567  | 95.9      | 655  | 95.3      | 649  | 95.7      |
| Healed  | Male   | 1    | 0.3       | 5    | 1.2       | 4    | 0.9       |
|         | Female | 3    | 0.9       | 3    | 0.7       | 5    | 1.1       |
| Sum     | Male   | 349  | 100       | 424  | 100       | 442  | 100       |
|         | Female | 591  | 100       | 687  | 100       | 678  | 100       |

Table 4. Multivariable logistic regression analysis for the presence of T2D

| Year     | Sex                               | Variables                         | B                                 | SE      | P         | OR        | 95% CI |       |       |

Refer to Table 2 with respect to the variables of B-3, B-4, B-5, B-6 and B-8.

Age, BMI, the habits of smoking, alcohol drinking and exercise, and the medication of  $\alpha$ -GI (only in the case of 2016) were used as the moderator variable.

The variables with  $p < 0.2$  were presented. \* indicate  $p < 0.05$ .

Abbreviations: SE, standard error; OR, odds ratio; CI, confidence interval.
