21 \*This article is dedicated to Professor Dr. J. P. van der Walt, South Africa for his excellent  
22 taxonomic study on the Lipomycetaceous yeasts, especially in the findings of *Zygozoma*  
23 *oligophaga* and its related species.

24 \*This work was presented at the 27th annual meeting of Japan Society for Microbial  
25 Resources and Systematics (JSMRS) on June 23-30, 2021 (Vu *et al.* 2021).

35  
36 **ABSTRACT**

37 In the family Lipomycetaceae, the seven genera *Waltomyces*, *Zygozoma*, *Babjevia*,  
38 *Smithiozoma*, *Kawasakia*, *Limtongia*, and *Kockiozoma* were introduced. However, all of  
39 them were neither accepted nor recognized. This paper described the historical surveys in  
40 the systematics of the Lipomycetaceous yeasts and confirmed the total of ten genera  
41 within the family, i.e., the genus *Lipomyces* sensu stricto (the type genus), the above-

42 mentioned seven genera, the monotypic genus *Dipodascopsis*, and the new genus  
43 *Neoaidaea* from the phylogenetic and the phenotypic points of view.

44

45

46 GRAPHICAL ABSTRACT

47

The family Lipomycetaceae Novak et Zolt

Genus

1. *Lipomyces* Lodder et Kreger-van Rij (1952) sensu stricto

2. *Dipodascopsis* Batra et Millner (1978)

3. *Waltomyces* Yamada et Nakase (1985)

4. *Zygozoma* van der Walt et von Arx (1987)

5. *Babjevia* van der Walt et Smith (1995)

6. *Smithiozoma* Kock, van der Walt et Yamada (1995)

7. *Kawasakia* Yamada et Nogawa (1995)

8. *Limtongia* Jindamorakot, Am-in, Yukphan et Yamada (2011)

9. *Kockiozoma* Jindamorakot, Yukphan et Yamada (2012)

10. *Neoaidaea* Vu, Yukphan, Tanasupawat et Yamada (202/)

Species

*L. starkeyi* (the type species), *L. kononenkoeae*, *L. tetrasporus*, *L. mesenbrius*, *L. spencermartinsiae*, *L. dorenjongii*, *L. kockii*, *L. yamadae*, *L. yarrowii*, *L. orientalis*, *L. chichibuensis*, *L. kalimantanensis*, *L. tropicalis*, *L. okinawaensis*

*D. uninucleata*

*W. lipofer*

*Z. oligophaga*

*B. anomala* (the type species), *B. hyphoforaminiformans*, *B. hyphasca*

*S. japonica*

*K. arxii*

*L. smithiae*

*K. suomiensis*

*N. tothii*

48

49

The family Lipomycetaceae Novak et Zolt

Genus

1. *Lipomyces* Lodder et Kreger-van Rij (1952) sensu Kurtzman, Albertyn et Basehoar-Powers (2007)

2. *Dipodascopsis* Batra et Millner (1978) emend. Kurtzman, Albertyn et Basehoar-Powers (2007)

Species

*L. starkeyi* (the type species), *L. kononenkoeae*, *L. tetrasporus*, *L. mesenbrius*, *L. spencermartinsiae*, *L. dorenjongii*, *L. kockii*, *L. yamadae*, *L. yarrowii*, *L. orientalis*, *L. chichibuensis*, *L. kalimantanensis*, *L. tropicalis*, *L. okinawaensis* (= the genus *Lipomyces* sensu stricto); *L. lipofer*, *L. oligophagus*, *L. japonicus*, *L. arxii*, *L. smithiae*, *L. suomiensis*

*D. uninucleata* (the type species), *D. tothii*, *D. anomala*

50

51

52

53

54 In the family Lipomycetaceae Novak et Zsolt, the seven genera *Waltomyces*, *Zygozoma*,  
55 *Babjevia*, *Smithiozoma*, *Kawasakia*, *Limtongia*, and *Kockiozoma* were once introduced  
56 (Yamada and Nakase 1985; van der Walt *et al.* 1987; Smith *et al.* 1995; Kock *et al.* 1995;  
57 Yamada and Nogawa 1995b; Jindamorakot *et al.* 2011, 2012). All of them were  
58 respectively taxonomic-homogeneous natured, i.e., morphologically, physiologically,  
59 chemotaxonomically, genetically, and phylogenetically. However, Kurtzman *et al.* (2007)  
60 divided the family into two, i.e., the monophyletic genus *Lipomyces* sensu and the  
61 paraphyletic genus *Dipodascopsis* emend. instead (Smith and de Hoog 2011; Smith and  
62 Kurtzman 2011).

63 This paper describes the historical surveys in the systematics of the Lipomycetaceous  
64 yeasts and covers the seven genera mentioned above as taxonomic criteria, in addition to  
65 the genus *Lipomyces* sensu stricto, the monotypic genus *Dipodascopsis* (Jindamorakot *et*  
66 *al.* 2011, 2012), and the new genus *Neoaidaea* (Vu *et al.* 2021) from the phylogenetic and  
67 the phenotypic points of view. Accordingly, the family is comprised of ten genera in total  
68 as follows.

69

70 The family Lipomycetaceae Novak et Zsolt  
71 The type genus is *Lipomyces* Lodder et Kreger van-Rij.  
72 Ten genera are included.

73

74 Genus I. *Lipomyces* Lodder et Kreger-van Rij sensu stricto  
75 The type species is *Lipomyces starkeyi* Lodder et Kreger-van Rij.  
76 Fourteen species are included.

- 77 1. *Lipomyces starkeyi* Lodder et Kreger-van Rij (1952)
- 78 2. *Lipomyces kononenkoeae* Nieuwdorp, Bos et Slooff (1974)
- 79 3. *Lipomyces tetrasporus* Nieuwdorp, Bos et Slooff (1974)
- 80 4. *Lipomyces mesembrius* Botha, van der Walt et Smith (1997)
- 81 5. *Lipomyces spencermartinsiae* (van der Walt et Smith) van der Walt et Smith (1997)  
82 Basionym: *Lipomyces kononenkoeae* Nieuwdorp, Bos et Slooff subsp. *spencermartinsiae*  
83 van der Walt et Smith (1995)
- 84 6. *Lipomyces doorenjongii* van der Walt et Smith (1999)
- 85 7. *Lipomyces kockii* Smith et van der Walt (1999)
- 86 8. *Lipomyces yamadae* van der Walt et Smith (1999)
- 87 9. *Lipomyces yarrowii* Smith et van der Walt (1999)
- 88 10. *Lipomyces orientalis* Thanh (2006)
- 89 11. *Lipomyces chichibuensis* Yamazaki et Kawasaki (2014)
- 90 12. *Lipomyces kalimantanensis* Kanti, Yamazaki et Kawasaki (2017)
- 91 13. *Lipomyces tropicalis* Kanti, Yamazaki et Kawasaki (2017)
- 92 14. *Lipomyces okinawensis* Yamazaki, Yanagiba et Naganuma (2017)

93

94 The species classified in the genus *Lipomyces* sensu stricto were tightly coupled with

95 one another in all the three phylogenetic trees based on the concatenated four-gene  
96 sequences of 18S rRNA, 26S rRNA, mitochondrial small subunit rRNA, and *EF1- $\alpha$*   
97 derived from the neighbour-joining, the maximum parsimony, and the maximum  
98 likelihood methods (Jindamorakot *et al.* 2012). On the other hand, the phylogenetic  
99 positions of the *Lipomyces* species newly designated by Kurtzman *et al.* (2007) were quite  
100 changeable in the monophyletic genus *Lipomyces* sensu (Jindamorakot *et al.* 2012). In  
101 fact, the resulting genus has an extremely wide range of DNA G+C contents (14.2 mol%,  
102 from 41.5 - 55.7 mol% G+C; Jindamorakot *et al.*, 2012) and three kinds of ubiquinone  
103 isoprenologues (Q-8, Q-9, and Q-10: Yamada 1986; Yamada *et al.* 1986). According to  
104 Nakase and Komagata (1970) and Yamada *et al.* (1973), such a genus was a taxonomically  
105 heterogeneous-natured taxon, just as found in the genus *Pichia* Hansen once designated.  
106

107 Genus II. *Dipodascopsis* Batra et Millner

108 *Dipodascopsis uninucleata* (Biggs) Batra et Millner (1978)

109 Basionym: *Dipodascus uninucleatus* Biggs (1937).

110 Two varieties are described.

111 1. *Dipodascopsis uninucleata* var. *uninucleata*

112 2. *Dipodascopsis uninucleata* var. *wickerhamii* Kreger-van Rij (1974)

113  
114 When the phylogenetic tree based on the 26S rRNA gene D1/D2 domain sequences was  
115 constructed by the neighbour-joining method, the paraphyletic genus *Dipodascopsis*  
116 emend. Kurtzman *et al.* was split into two and produced a monotypic genus (Fig. 1), as  
117 reported previously (Jindamorakot *et al.* 2011, 2012), indicating that *D. uninucleata*, *D.*  
118 *tothii* and *D. anomala* were not tightly coupled within the genus *Dipodascopsis* emend.

119 Such a phylogenetic data was also given by Kurtzman (2011), i.e., the phylogenetic tree  
120 based on the concatenated three-gene sequences of 26S rRNA, 18S rRNA, and *EF1- $\alpha$*   
121 derived from the neighbour-joining method represented that *D. uninucleata* was connected  
122 first to *L. starkeyi* but not to *D. anomala* (= *B. anomala*) and then the resulting cluster was  
123 done to *D. anomala*. In fact, the calculated sequence similarity (95.7%) between *D.*  
124 *uninucleata* and *L. starkeyi* was much higher than that (90.4%) between *D. uninucleara* and  
125 *B. anomala* (Table 1).  
126

127 Genus III. *Waltomyces* Yamada et Nakase (MB 25779)

128 *Waltomyces lipofer* (Lodder et Kreger-van Rij ex Slooff) Yamada et Nakase (1985) (MB  
129 103899)

130 Basionym: *Lipomyces lipofer* Lodder et Kreger-van Rij (1952) ex Slooff (1970).  
131

132 The three partial base sequencings in positions 468-622, 155 bases (designated as  
133 region *a*) and in positions 1611-1835, 225 bases (designated as region *b*) of 26S rRNA and  
134 in positions 1451-1618, 168 bases (designated as region *c*) of 18S rRNA showed that the  
135 Q10-equipped species, *W. lipofer* had 88% maximum homology in region *a*, along with *B.*

136 *anomala* (= *D. anomala*), to *L. starkeyi*, *L. tetrasporus* and *L. kononenkoae* in the genus  
137 *Lipomyces* sensu stricto (Yamada and Nogawa 1995a). In contrast, the above-mentioned  
138 three *Lipomyces* species constituted a cluster with 97% or more maximum homologies  
139 within the genus, indicating that the species is accommodated to a different genus from the  
140 genus *Lipomyces* sensu stricto (Table 1). Such similar experimental data were shown,  
141 since the species was used as outgroup in the phylogenetic trees concerned (Kurtzman *et*  
142 *al.* 2007; Yamazaki and Kawasaki 2014).

143

144 Genus IV. *Zygozoma* van der Walt et von Arx (MB 25149)

145 *Zygozoma oligophaga* van der Walt et von Arx (1987) (MB 131108)

146 Synonym: *Lipomyces oligophagus* (van der Walt et von Arx) Kurtzman, Albertyn et  
147 Basehoar-Powers (2007).

148

149 Four *Zygozoma* species were reported (van der Walt *et al.* 1987, 1989b, 1990; Smith *et*  
150 *al.* 1989). However, the four species were not tightly coupled with one another in the  
151 phylogenetic trees based on the concatenated four-gene sequences derived from the three  
152 methods, i.e., the neighbour-joining, the maximum parsimony, and the maximum  
153 likelihood methods (Jindamorakot *et al.* 2012) and chemotaxonomically grouped into two  
154 based on the ubiquinone isoprenologues, i.e., Q-8 and Q-9 (Fig. 1) (Yamada and Nogawa  
155 1995a; Jindamorakot *et al.* 2011, 2012). Especially, the Q8-equipped species, *Z.*  
156 *oligophaga* had extremely long branches (Fig. 1) (Jindamorakot *et al.* 2012) and quite low  
157 sequence similarities (81.6-86.6%) (Table 1).

158

159 Genus V. *Babjevia* van der Walt et Smith (MB 27435)

160 The type species is *Babjevia anomala* (Babjeva et Gorin) van der Walt et Smith.

161 Three species are included.

162 1. *Babjevia anomala* (Babjeva et Gorin) van der Walt et Smith (1995) (MB 363215)

163 Basionym: *Lipomyces anomalus* Babjeva et Gorin (1975).

164 Synonym: *Dipodascopsis anomala* (Babjeva et Gorin) Kurtzman, Albertyn et Basehoar-  
165 Powers (2007).

166 2. *Babjevia hyphoforaminiformans* Yamazaki, Lorliam et Kawasaki (2020) (MB  
167 829051)

168 3. *Babjevia hyphasca* Yamazaki, Lorliam et Kawasaki (2020) (MB 829053)

169

170 Kurtzman *et al.* (2007) accommodated *B. anomala* to the paraphyletic genus  
171 *Dipodascopsis* emend. as *D. anomala*. However, Jindamorakot *et al.* (2012) insisted that the  
172 species, *D. anomala* should be transferred again to the genus *Babjevia* as *B. anomala*,  
173 since the species was not tightly coupled with the type species, *D. uninucleata* (Fig. 1). In  
174 fact, Yamazaki *et al.* (2020) classified two new species to the genus *Babjevia* but not to the  
175 genus *Dipodascopsis*, as already suggested by Jindamorakot *et al.* (2012).

176 In the phylogenetic tree based on the concatenated four-gene sequences derived from the

177 maximum likelihood method (Yamazaki *et al.* 2020), it is reasonable that the names of  
178 species, *L. lipofer*, *L. smithiae*, *Zygozoma arxii* (= *L. arxii*), *L. japonicus*, *L. oligophaga*  
179 [sic], and *Zygozoma suomiensis* (= *L. suomiensis*) should be changed to *Waltomyces*  
180 *lipofer*, *Limtongia smithiae*, *Kawasakia arxii*, *Smithiozoma japonica*, *Zygozoma*  
181 *oligophaga*, and *Kockiozoma suomiensis* respectively since the generic name of *Babjevia*  
182 was revived.

183

184 Genus VI. *Smithiozoma* Kock, van der Walt et Yamada (MB 27638)

185 *Smithiozoma japonica* (van der Walt, Smith, Yamada et Nakase) Kock, van der Walt et  
186 Yamada (1995) (MB 414161)

187 Basionym: *Lipomyces japonicus* van der Walt, Smith, Yamada et Nakase (1989).

188

189 In the three partial base sequencings mentioned above, the Q9-equipped species, *S.*  
190 *japonica* (= *L. japonicus*; van der Walt *et al.* 1989a) represented 89% maximum homology  
191 in region *a*, two base differences in region *b* and five base differences in region *c* to *L.*  
192 *starkeyi*, *L. tetrasporus* and *L. kononenkoeae* in the genus *Lipomyces* sensu stricto. In  
193 contrast, the above-mentioned three *Lipomyces* species constituted clusters with 97% or  
194 more maximum homologies (region *a*) and no base differences (regions *b* and *c*) within  
195 the genus (Yamada and Nogawa 1995a), indicating that the species is accommodated  
196 taxonomically to a different genus from the genus *Lipomyces* sensu stricto (Table 1). In the  
197 phylogenetic trees based on the concatenated four-gene sequences, *S. japonica* was not  
198 tightly coupled, i.e., the species was connected to the cluster comprised of the Q9-  
199 equipped species including *L. starkeyi*, *D. uninucleata* and so on, when constructed by the  
200 neighbour-joining method, but to the cluster of Q8-equipped species including *Z.*  
201 *oligophaga* and *Kockiozoma suomiensis*, when constructed by the maximum parsimony  
202 method (Jindamorakot *et al.* 2012).

203

204 Genus VII. *Kawasakia* Yamada et Nogawa (MB 27831)

205 *Kawasakia arxii* (van der Walt, Smith et Yamada) Yamada et Nogawa (1995) (MB  
206 442988)

207 Basionym: *Zygozoma arxii* van der Walt, Smith et Yamada (1989).

208 Synonym: *Lipomyces arxii* (van der Walt, Smith et Yamada) Kurtzman, Albertyn et  
209 Basehoar-Powers (2007).

210

211 The Q9-equipped species, *Kawasakia arxii* was very unique in representing  
212 considerably large base differences (six) to the above-mentioned three *Lipomyces* species  
213 in the partial base sequencing of 18S rRNA (region *c*), in contrast to *W. lipofer*, which had  
214 only one base difference in the same region (Yamada and Nogawa 1995a, b). In the  
215 remaining regions *a* and *b*, the maximum homology and the base differences of the species  
216 were 93% and only one. The calculated 26S rRNA gene D1/D2 domain sequence  
217 similarities of *Kawasakia arxii* were 85.7 - 97.5% (Table 1). In the phylogenetic trees

218 based on the concatenated four-gene sequences, the phylogenetic positions of *Kawasakia*  
219 *arxii* were considerably changeable, indicating that the species was not tightly coupled to  
220 any of other species (Jindamorakot *et al.* 2012).

221

222 Genus VIII. *Limtongia* Jindamorakot, Am-in, Yukphan et Yamada (MB 582716)

223 *Limtongia smithiae* (van der Walt, Wingfield et Yamada) Jindamorakot, Am-in,

224 Yukphan et Yamada (2011) (MB 582717)

225 Basionym: *Zygozoma smithiae* van der Walt, Wingfield et Yamada (1990).

226 Synonym: *Lipomyces smithiae* (van der Walt, Wingfield et Yamada) Kurtzman,

227 Albertyn et Basehoar-Powers (2007).

228

229 In the three partial base sequencings mentioned above, the Q9-equipped species,  
230 *Limtongia smithiae* represented 89% maximum homology, four base differences and three  
231 base differences respectively to *L. starkeyi*, *L. tetrasporus* and *L. kononenkoe* in the  
232 genus *Lipomyces* sensu stricto (Yamada and Nogawa 1995a). The calculated 26S rRNA  
233 gene D1/D2 domain sequence similarities of the species were 82.9 - 92.4%, indicating that  
234 the species is accommodated to an independent genus (Table 1).

235

236 Genus IX. *Kockiozoma* Jindamorakot, Yukphan et Yamada (MB 587737)

237 1. *Kockiozoma suomiensis* (Smith, van der Walt et Yamada) Jindamorakot, Yukphan et

238 Yamada (2012) (MB 587754)

239 Basionym: *Zygozoma suomiensis* Smith, van der Walt et Yamada (1990).

240 Synonym: *Lipomyces suomiensis* (Smith, van der Walt et Yamada) Kurtzman, Albertyn

241 et Basehoar-Powers (2007).

242 2. *Kockiozoma yamanashiensis* f.a. (Yamazaki, Yanagiba et Naganuma) comb. nov.

243 Basionym: *Lipomyces yamanashiensis* f.a. Yamazaki, Yanagiba et Naganuma, Int. J.

244 Syst. Evol. Microbiol. 67, 2945, 2017.

245 The type strain is NBRC 110621<sup>T</sup> = CBS 14748<sup>T</sup>.

246

247 In the three partial base sequencings mentioned above, the Q8-equipped species,  
248 *Kockiozoma suomiensis* represented 83% maximum homology, 12 base differences and  
249 four base differences respectively to *L. starkeyi*, *L. tetrasporus* and *L. kononenkoe* in the  
250 genus *Lipomyces* sensu stricto (Yamada and Nogawa 1995a). The calculated 26S rRNA  
251 gene D1/D2 domain sequence similarities of the species were 85.9 - 90.6%, indicating that  
252 the species is accommodated to an independent genus (Table 1).

253

254 *Dipodascopsis tothii* and *B. anomala* (= *D. anomala*) were tightly coupled in the three  
255 phylogenetic trees (Jindamorakot *et al.* 2012), so that the two species appeared to be  
256 classified in a single genus (Fig. 1). Due to the priority of *B. anomala*, the single genus  
257 was to be named *Babjevia*. However, the distance between the two species, *D. tothii* and  
258 *B. anomala* was not so short, when compared with *Kluyveromyces polysporus* (=

259 *Vanderwaltozyma polyspora*) and *Saccharomyces cerevisiae* (Jindamorakot *et al.* 2012). In  
260 fact, the calculated pair-wise sequence similarity (95.6%) between the two species was  
261 interestingly almost the same as that (95.7%) between *D. uninucleata* and *L. starkeyi* and  
262 that (95.2%) between *W. lipofer* and *L. starkeyi* and not so high to accommodate the two  
263 species to the single genus *Babjevia* (Table 1), indicating that an additional genus can be  
264 phylogenetically introduced for *D. tothii*. Phenotypically, the species was quite different  
265 from *B. anomala*, e.g., in the morphology of asci and ascospores and the mode of asexual  
266 reproduction (Smith and de Hoog 2011).

267 Yamazaki *et al.* (2017a, b) constructed the phylogenetic trees based on the translation  
268 elongation factor 1-alpha (*EF1- $\alpha$* ) gene sequences derived from the neighbour-joining  
269 method. In the phylogenetic trees, it is of interest that *D. tothii* was found inside and  
270 distantly separated from *B. anomala* as well as *D. uninucleata*. In contrast, the cluster  
271 including *L. starkeyi* and its relatives and the cluster including *Kockiozyma suomiensis* and  
272 its related *Myxozyma* species were tightly coupled without any exception. In this respect,  
273 *D. tothii* was quite different phylogenetically from the remaining two species of the  
274 paraphyletic genus *Dipodascopsis* emend., and thus the introduction of a separate new  
275 genus was confirmed (Vu *et al.* 2021).

276

277 Genus X. *Neoaidaea* Vu, Yukphan, Tanasupawat et Yamada gen. nov.

278 *Neoaidaea* (Ne.o.a.i'da.e.a. N. L. fem. n. *Neoaidaea*, new Aida, in honour of Dr. Ko  
279 Aida, Professor Emeritus, The Institute of Applied Microbiology, The University of  
280 Tokyo, Tokyo, Japan, who introduced the isoprenoid quinone analyses into the microbial  
281 systematics.

282 The colonies are cream-coloured, moist and creamy after 10 d (Smith and de Hoog  
283 2011). Budding cells are absent. Hyphae are firm with inflated cells and intensely  
284 amyloid. Arthroconidia are absent. Gametangia are formed laterally on hyphae as curved  
285 branches. Asci arise after fusion of a terminal cell with its penultimate cell. Asci are  
286 acicular, 50 - 100  $\mu\text{m}$  long and contain 30 - 100 ascospores. Asci open by rupturing at the  
287 apex. Ascospores are subhyaline to hyaline, broadly ellipsoidal, occasionally bean-shaped,  
288  $1 \times 1.5 - 2 \mu\text{m}$  and without slime. Fermentation is absent. Grows on glucose, inulin,  
289 sucrose, raffinose, galactose, lactose, trehalose, maltose, methyl- $\alpha$ -glucoside, starch,  
290 cellobiose, salicin, L-sorbose, xylose, arabinose, L-arabinose, ethanol, glycerol, ribitol,  
291 mannitol, glucitol, *myo*-inositol, succinate (w), and gluconate (v), but not on melibiose, L-  
292 rhamnose, ribose, methanol, erythritol, galactitol, and DL-lactate. No growth on vitamin-  
293 free medium (Smith and de Hoog 2011). Ubiquinone-9 (Q-9) is present (Cottrell and Kock  
294 1989).

295 Mycobank number is MB/////////.

296 *Neoaidaea tothii* (Zolt 1963) Vu, Yukphan, Somboon et Yamada comb. nov.

297 Basionym: *Dipodascus tothii* Zolt (1963).

298 Synonym: *Dipodascopsis tothii* (Zolt 1963) Batra et Millner (1978).

299 The characteristics of the species are the same as those described in the genus (Smith

300 and de Hoog 2011).

301 The holotype is CBS 759.85<sup>T</sup> = NBRC 10813<sup>T</sup>.

302 MycoBank number is MB/////////.

303

304 For the detailed characteristics of the taxa mentioned above and the type strains

305 concerned, refer to the related monographs and/or articles.

306

307 Kurtzman (2003) introduced ‘clade’ or ‘phylogenetic circumscribed genus’ as generic  
308 concept. However, it was not yet perfect to get the taxonomic homogeneous-natured taxon  
309 for the genus. Namely, the branch lengths should be additionally considered in the  
310 phylogenetic trees.

311

312 In the seven ranks used for the systematics of plants and animals, the homogeneous-  
313 natured taxa can be available only when the lower-ranked two taxa, i.e., species and genus  
314 are dealt with taxonomically. Therefore, the present authors naturally selected the  
315 homogeneous-natured taxon in the generic designation, since the longer the phylogenetic  
316 distances are the more taxonomic heterogeneities will be increased.

317

318 Thus, the monophyletic genus *Lipomyces* Lodder et Kreger-van Rij sensu Kurtzman et  
319 al. (2007) contained the phylogenetic-distant and the phenotypic-different species such as  
320 *Waltomyces lipofer*, *Zygozoma oligophaga*, *Smithiozoma japonica*, *Kawasakia arxii*,  
321 *Limtongia smithiae*, and *Kockiozoma suomiensis*, all of which were classified as junior  
322 subjective synonyms of *L. lipofer*, *L. oligophagus*, *L. japonicus*, *L. arxii*, *L. smithiae*, and  
323 *L. suomiensis* respectively, in addition to *L. starkeyi*, the type species and its closely  
324 related *Lipomyces* species, which constituted the genus *Lipomyces* sensu stricto, and so  
325 corresponded exactly to the so-called family Lipomycetaceae (Jindamorakot *et al.* 2011,  
326 2012). On the other hand, the paraphyletic genus *Dipodascopsis* Batra et Millner emend.  
327 Kurtzman et al. (2007) was a monotypic genus, which included only *D. uninucleata*  
328 (Jindamorakot *et al.* 2012). For the remaining two species, one was transferred again to  
329 the genus *Babjevia* as *B. anomala* (Jindamorakot *et al.* 2012; Yamazaki *et al.* 2020) and  
330 the other was classified in the new genus *Neoaidea* as *Neoaidea tothii* gen. nov., comb.  
331 nov. (Vu *et al.* 2021).

332

333 Acknowledgements

334 The present authors express their sincere thanks for citing a number of articles for detailed  
335 discussions. Thanks are also due to Dr. M. Smith, The Netherlands for her valuable  
336 suggestions.

337

338 Funding information

339 The authors received no specific grant from any funding agency.

340

341 Conflicts of interest  
342 The authors declare that there are no conflicts of interest.  
343  
344 Author contributions  
345 Y.Y., H.T.L.V., P.Y., and S.T. designed the study. H.T.L.V. performed the main  
346 experiments. P.Y. instructed how to make the experiments. Y.Y. prepared the manuscript.  
347 The detailed discussion was made among Y.Y., H.T.L.V., P.Y., and S.T.

Table 1. The pair-wise 26S rRNA gene D1/D2 domain sequence similarity.

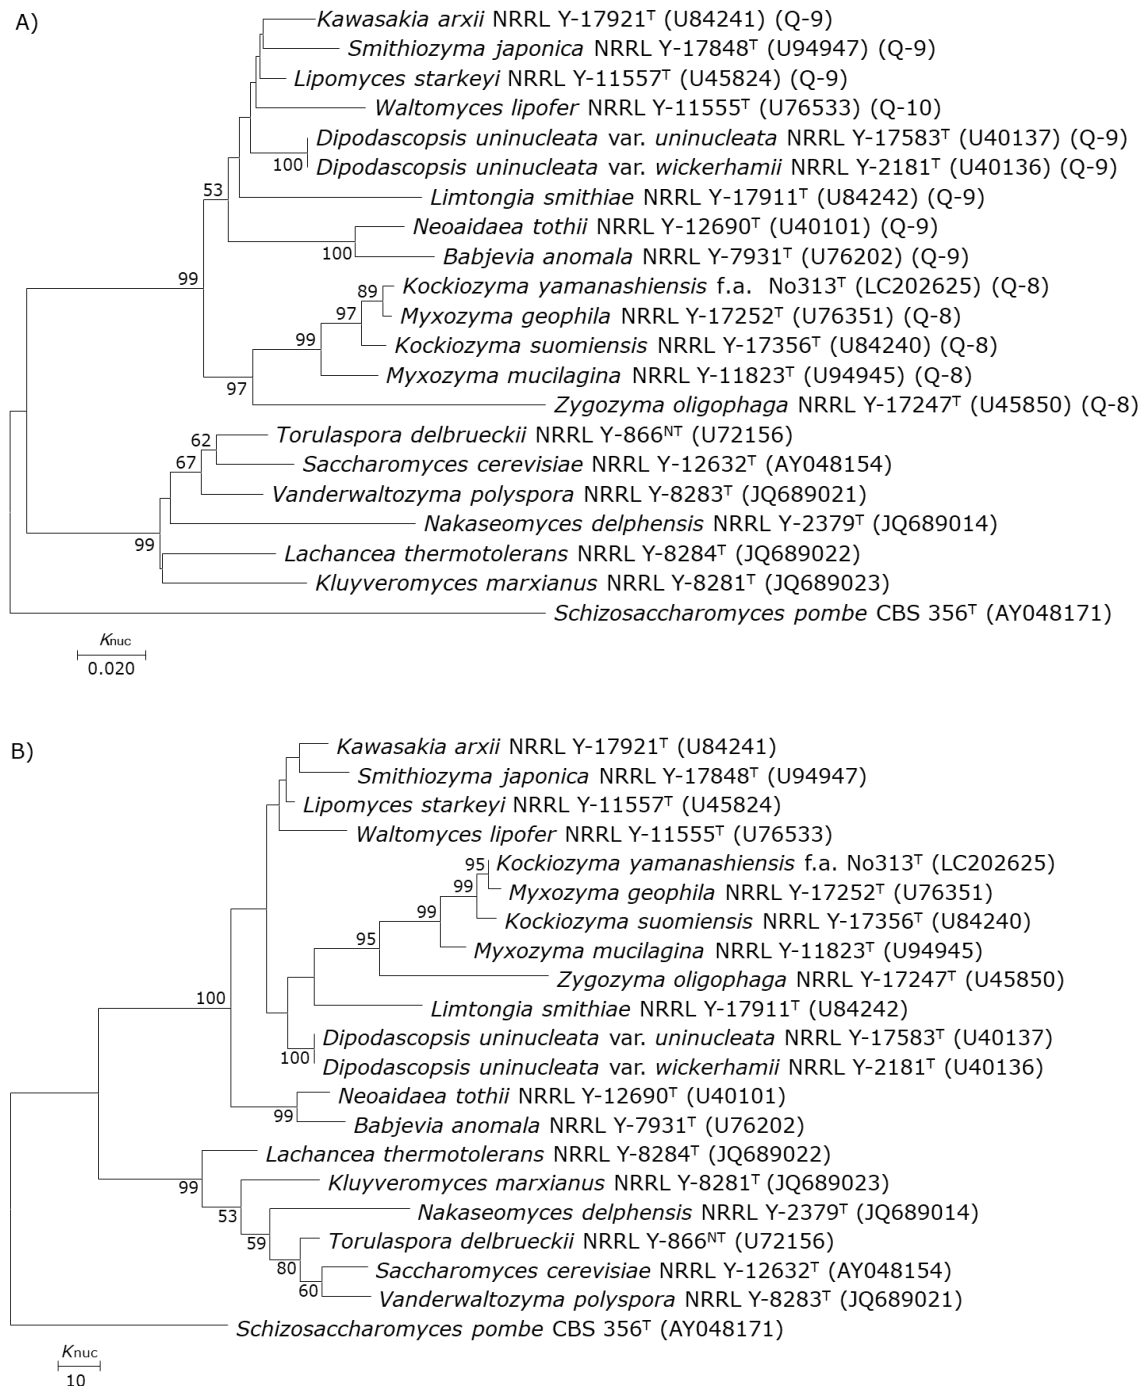

Species	Sequence similarity (%)											
	1	2	3	4	5	6	7	8	9	10	11	
1. <i>Lipomyces starkeyi</i>												
2. <i>Waltomyces lipofer</i>	95.2											
3. <i>Zygozoma oligophaga</i>	85.5	83.0										
4. <i>Babjevia anomala</i>	91.7	91.0	81.6									
5. <i>Smithiozoma japonica</i>	96.4	93.6	85.5	89.9								
6. <i>Kawasakia arxii</i>	97.5	94.1	85.7	92.2	95.7							
7. <i>Limtongia smithiae</i>	92.4	89.9	82.9	86.8	90.6	91.0						
8. <i>Kockiozoma suomiensis</i>	90.6	88.9	85.9	86.2	90.3	90.6	86.4					
9. <i>Myxozyma geophila</i>	90.4	89.0	86.6	85.9	90.4	90.3	85.7	98.0				
10. <i>D. uninucleata</i> var. <i>uninucleata</i>	95.7	94.0	85.5	90.4	95.0	95.4	91.2	90.2	90.2			
11. <i>D. uninucleata</i> var. <i>wickerhamii</i>	95.6	93.8	85.4	90.3	94.9	95.2	91.0	90.1	90.1	99.8		
12. <i>Neoaidaea tothii</i>	92.6	90.5	83.4	95.6	90.1	95.2	87.8	87.8	86.7	90.6	90.5	

*D. uninucleata*; *Dipodascopsis uninucleata*: The type strains were used of the respective species.

The pair-wise 26S rRNA gene D1/D2 domain sequence similarities were calculated for 555-568 bases with the program BioEdit (version 7.2.5) (Hall, *GERF Bull Biosci* 2011; **2**: 60).

Fig. 1. The phylogenetic relationships of the Lipomycetaceous yeast species. The phylogenetic trees based on the 26S rRNA gene D1/D2 domain sequences (526 bases) were constructed for the Lipomycetaceous yeast species by the neighbour-joining method (A) and by the maximum parsimony method (B). *Saccharomyces cerevisiae* and its related species were utilized for reference standards. *Schizosaccharomyces*

451 *pombe* was used as outgroup. The evolutionary distances were computed using the Kimura 2-parameter  
452 method (Kimura, *J Mol Evol* 1980; **16**: 111). The numerals at the nodes of the respective branches indicate  
453 bootstrap values (%) deduced from 1000 replications (Felsenstein, *Evolution* 1985; **39**: 783). The bootstrap  
454 values below 50% were deleted. For the additional phylogenetic trees based on the concatenated four-gene  
455 sequences, i.e., 18S rRNA, 26S rRNA, mitochondrial small subunit rRNA, and *EF1- $\alpha$* , derived from the  
456 three methods, refer to Jindamorakot *et al.* (2012). According to the theory of Kurtzman *et al.* (2007), the  
457 Lipomycetaceous yeast species are designated as *Lipomyces lipofer*, *L. oligophagus*, *L. japonicus*, *L.*  
458 *smithiae*, *L. arxii*, *L. suomiensis*, *Dipodascopsis uninucleata*, *D. anomala*, and *D. tothii* instead.
